- 4. Conclusion**

1. Background

International standards framework for autonomous vehicle safety

ADS : Automated Driving System
ODD: Operational Design Domain

WP29 Harmonization Forum GRVA

ADS shall not, while engaged, cause:

- **unreasonable risks** within their ODD.
- **reasonably foreseeable and preventable traffic accidents** within their ODD.

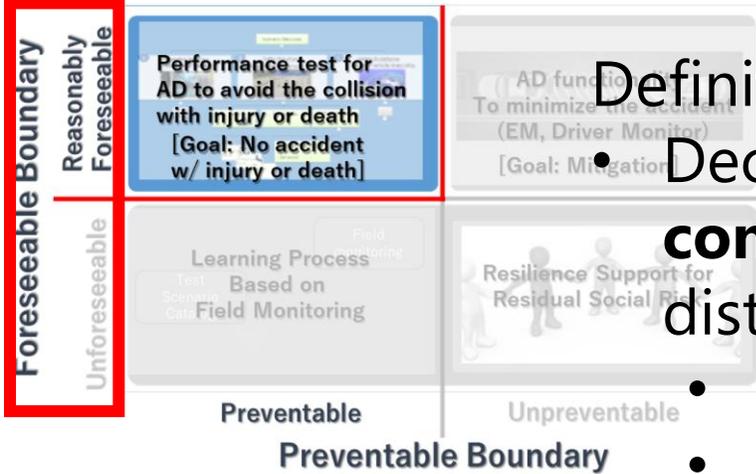

【Goal of SAKURA project】

- Analysis of the reasonably foreseeable and preventable scope in traffic disturbance scenarios under ADS safety requirements.

Focus on reasonably foreseeable and preventable domain

2. Scenario structure

Reasonably foreseeable boundary

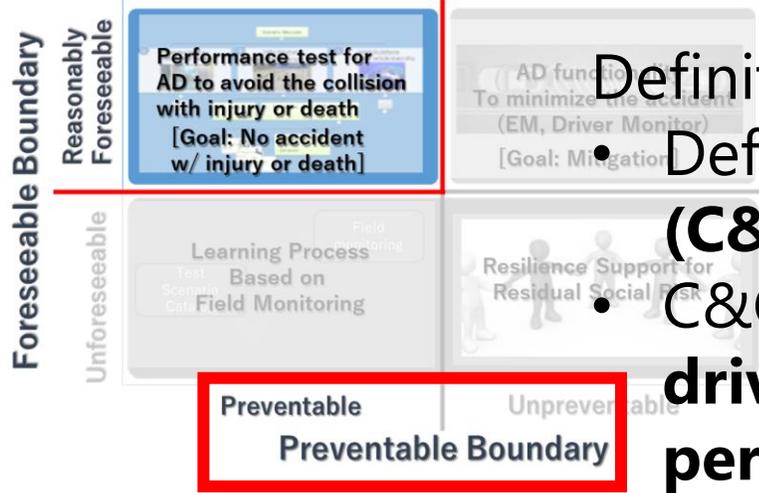

Definition of the **reasonably foreseeable boundary**

• Decompose the driving task into **perception, judgement, and control**, and define a structured taxonomy of scenarios involving disturbances:

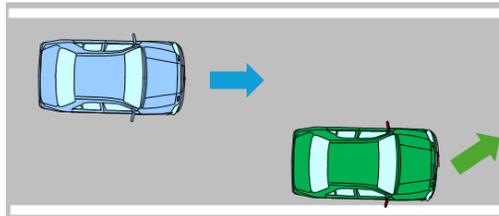

- **Perception disturbances**
- **Traffic disturbances**
- **Vehicle control disturbances**
- For each scenario, define representative parameters and determine their **reasonably foreseeable parameter ranges** based on real-world traffic data and other evidence

Establishes the scope of reasonably foreseeable parameter ranges based on empirical evidence.

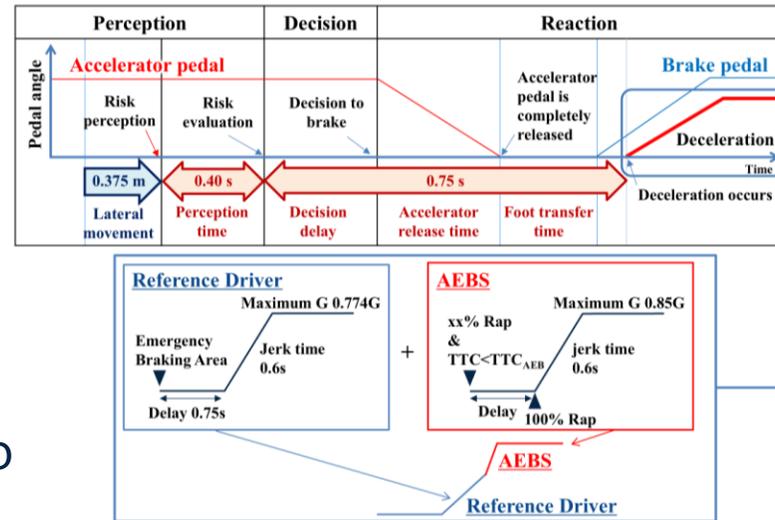

Definition of the **preventable boundary**

- Define as the range of conditions that a **Competent and Careful (C&C) Human Driver** would be able to avoid.
- C&C driver represents a modeled driver with a **certain level of driving competence, statistically satisfying a defined performance threshold.**

Model in cut-in scenario

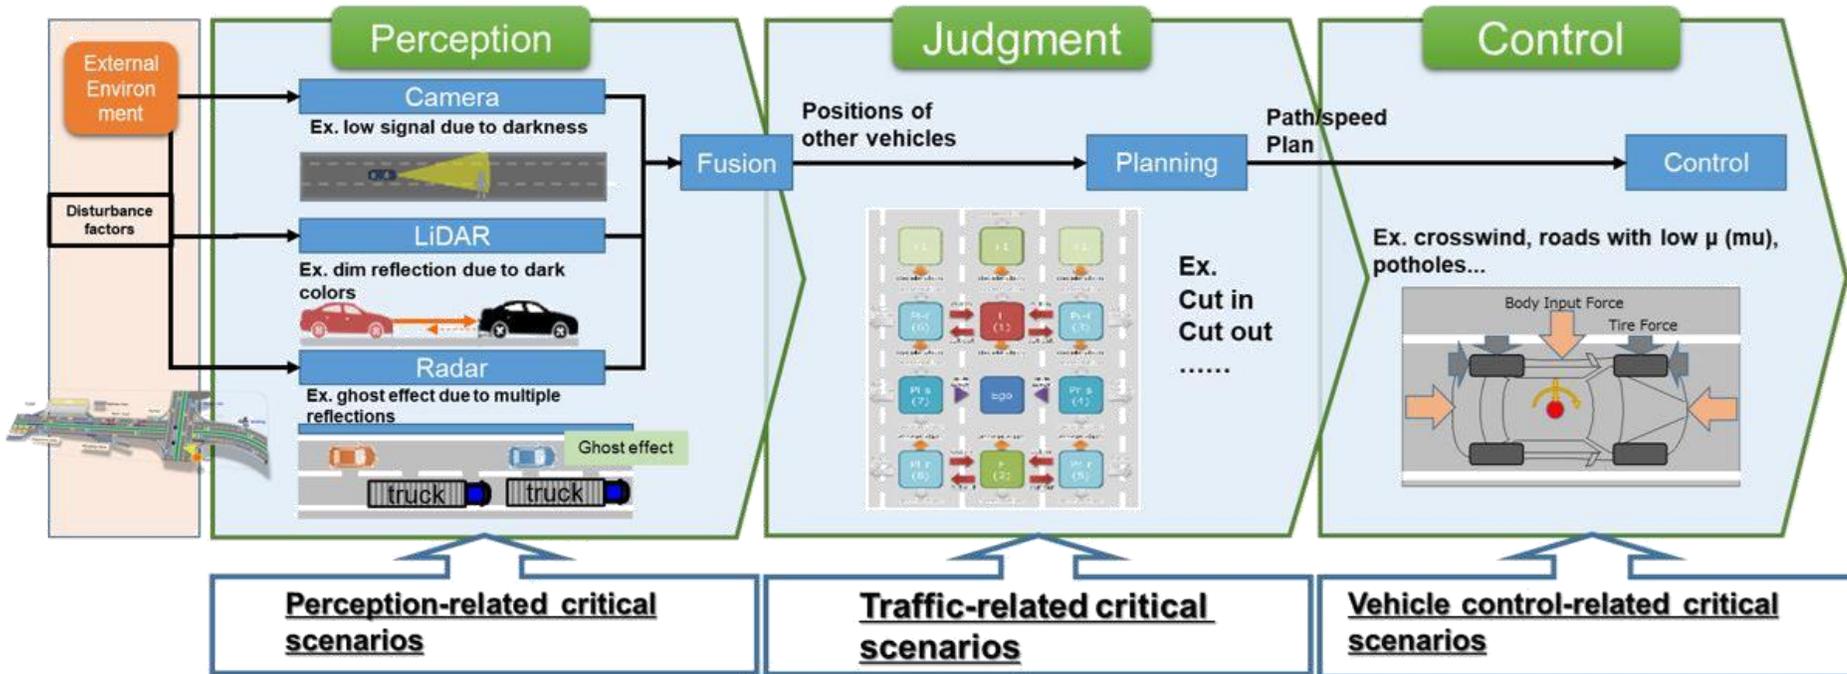

20

Establishes a human-based reference level for safety performance within the foreseeable scope.

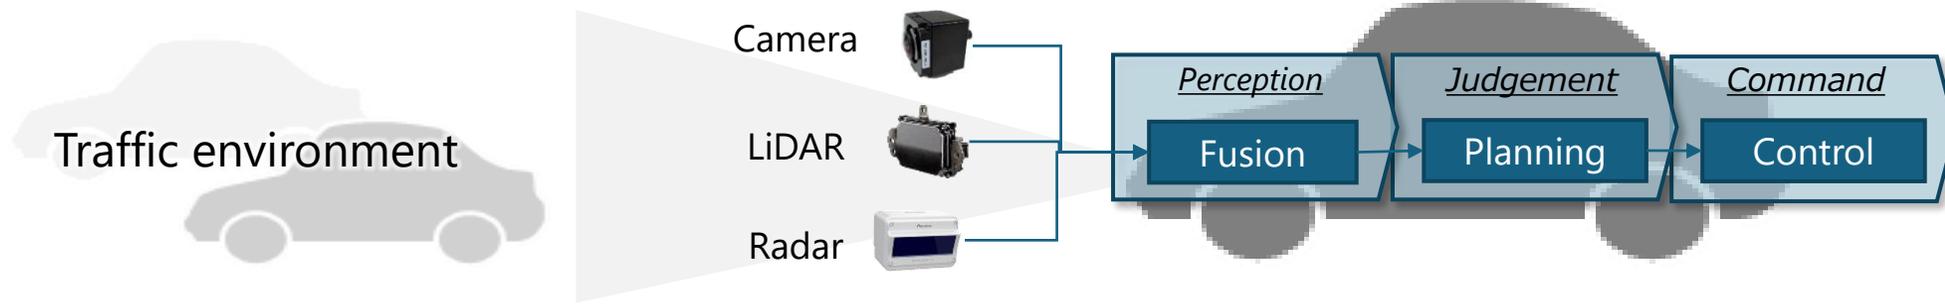

Concept of safety evaluation scenarios

- ◆ Decompose the dynamic driving task into three independent elements
- ◆ Define critical conditions within each element
- ◆ Combine the three elements to construct evaluation scenarios
- ◆ This framework has been incorporated into the international standard ISO 34502

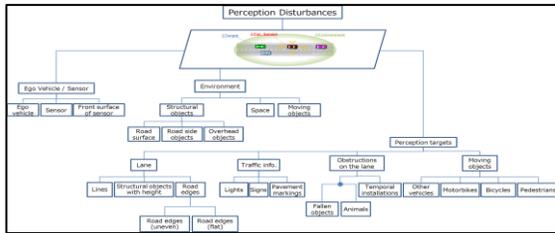

Safety evaluation begins with the structured decomposition of perception, judgment, and control.

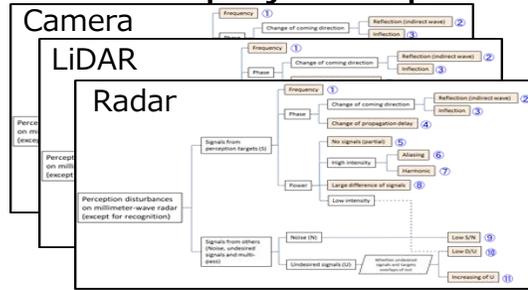

Perception disturbance scenarios consist of environmental factors and sensor physical principles.

Environmental factor

Sensor physical principle

Evaluation scenario

	Physical principles (Perception of signals/ Sensor orientation)													Physical principles (Recognition process)	
	Signals from perception targets (S)										Signals from others		Recognition process		
	Phase	Change of coming direction			Change of propagation delay		Power		Noise (N)	Undesired signals (U)					
Frequency	reflection (indirect wave)	refraction	diffraction	Change of propagation delay	to signals (partial)	High intensity	Alasing	harmonic	Large difference of signals	Low S/N	Low D/U	Increasing of U			
Ego vehicle / Sensor															
Front surface of sensor															
Road surface															
Roadside objects															
Overhead objects															
Space															
Moving objects															
Lines															
Structural objects with height															
Road edges															

Limited evaluation scenarios based on sensor malfunction principle

Perception disturbance scenarios consist of environmental factors and sensor physical principles.

Traffic disturbance scenarios organize and combine physical factors related to safety.

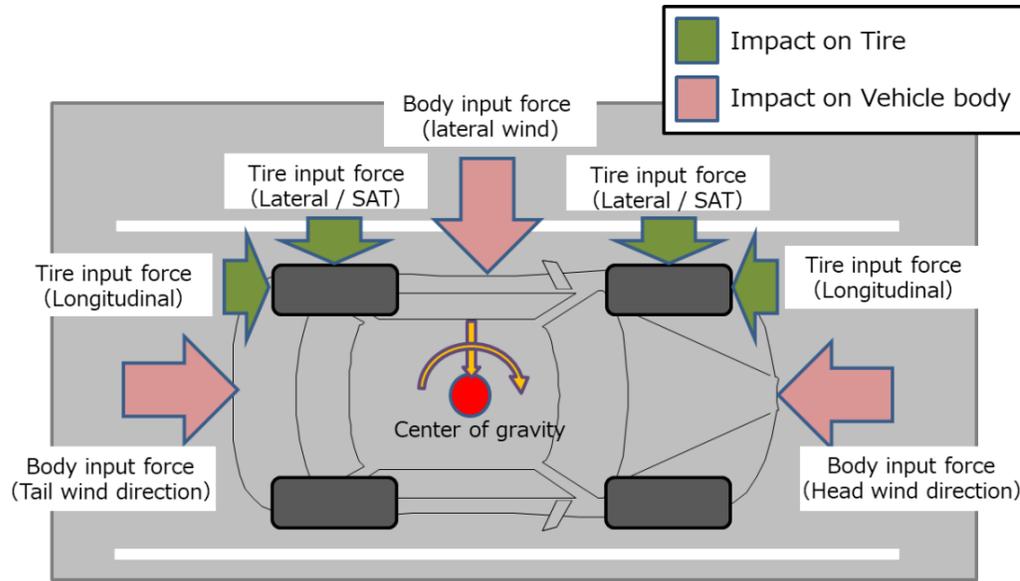

▶ Extract exhaustive and finite scenarios

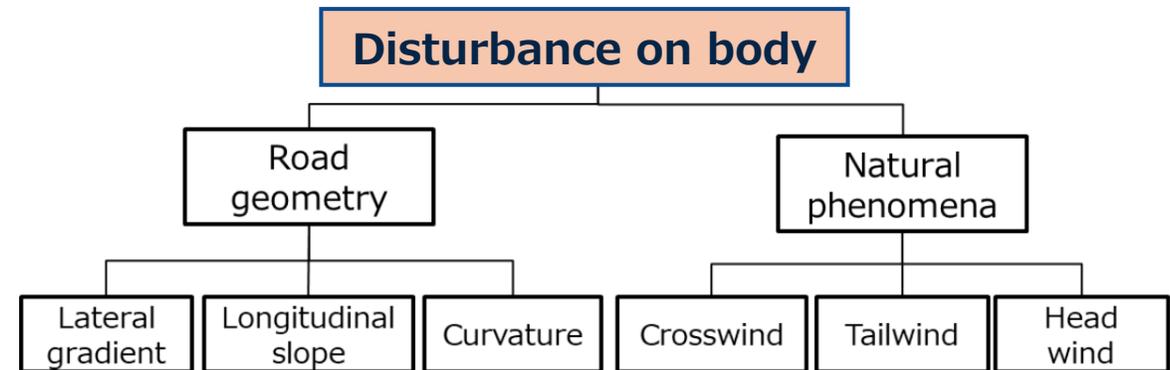

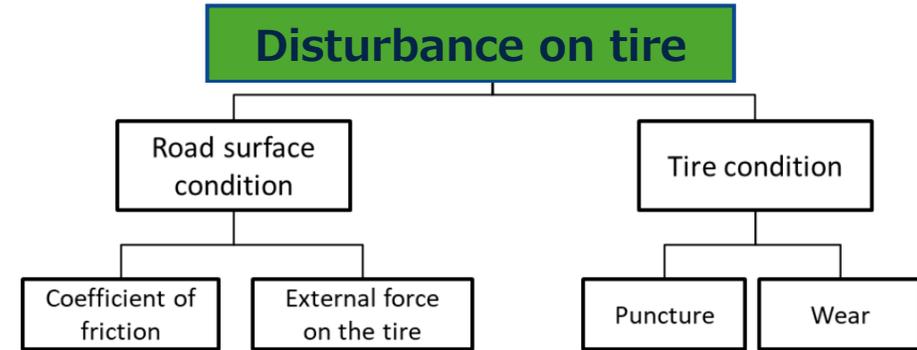

Vehicle specific traffic-related critical scenario structure schematic

Traffic disturbance scenarios consist of road geometry, vehicle positions, and vehicle behaviors.

Vehicle dynamics disturbance scenarios are divided into two main categories: tire-related and body-related disturbances.

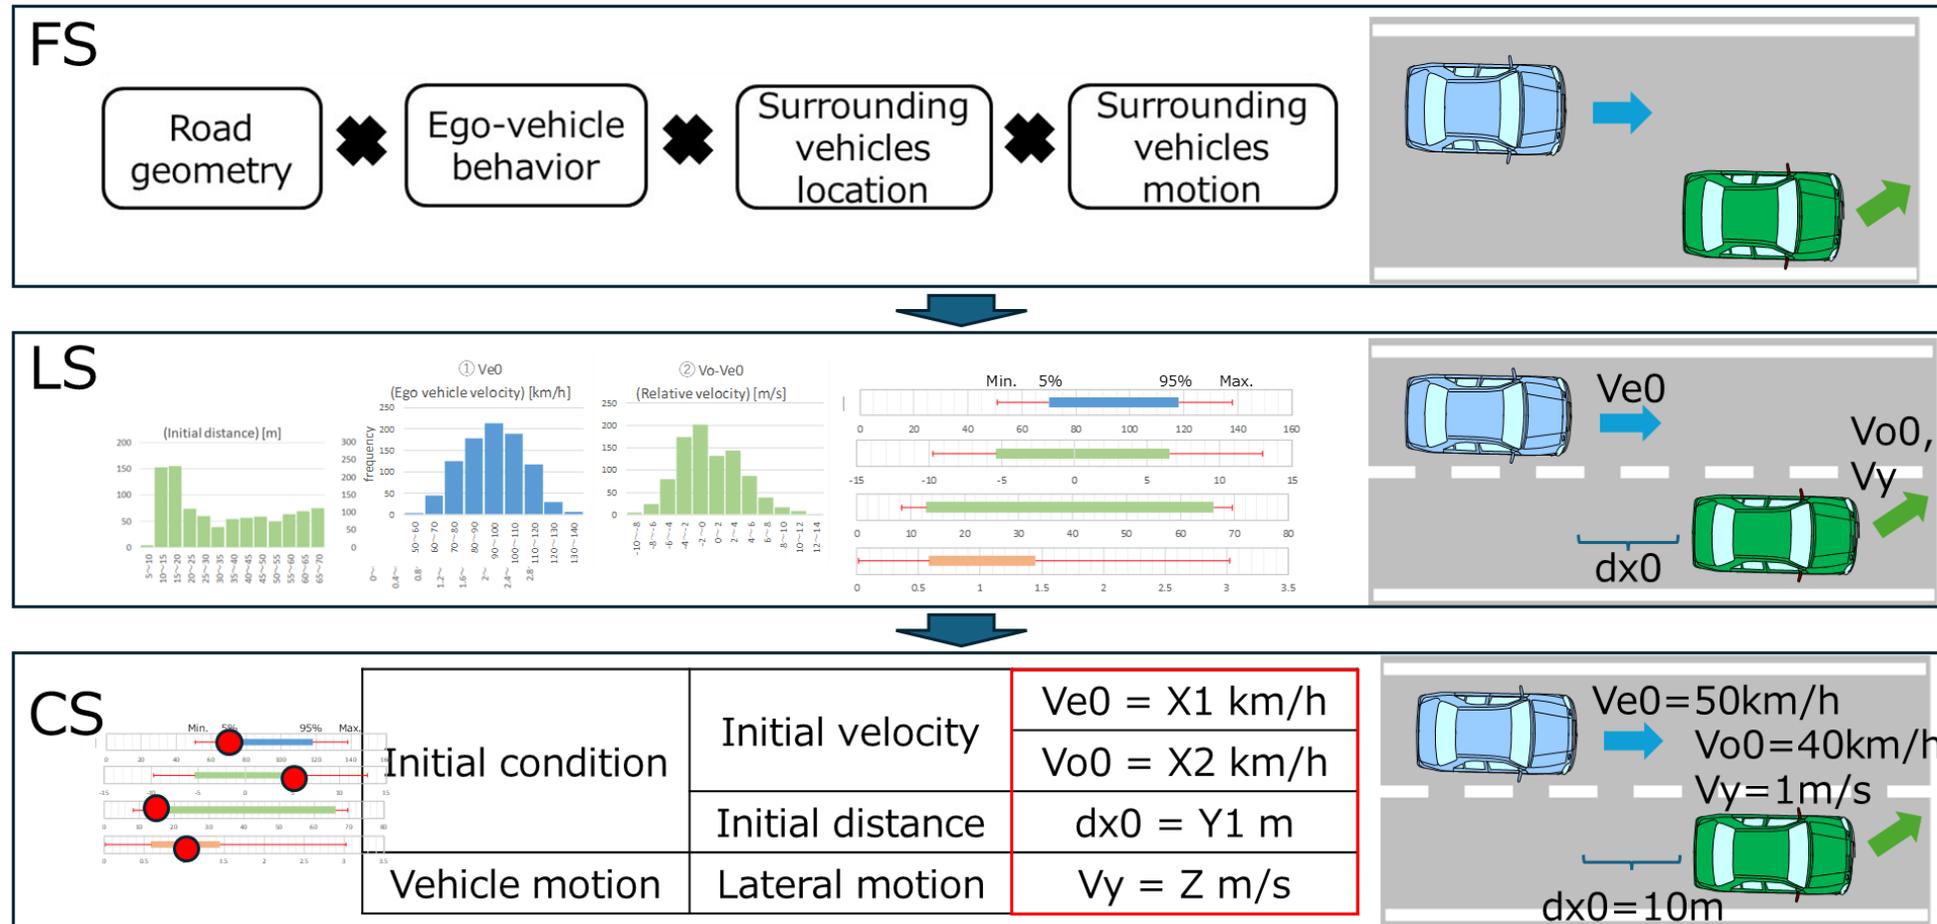

Physical principle of vehicle dynamics

The vehicle dynamics disturbance scenarios consist of tire factor and vehicle body factor.

Three layers of scenario abstraction

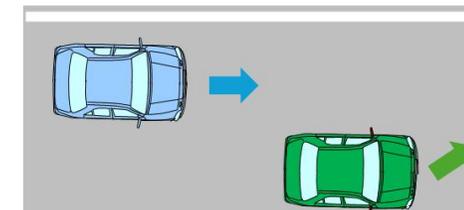

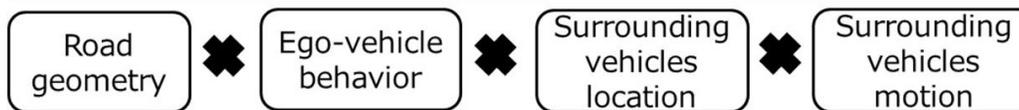

Each disturbance category follows the same three-layer abstraction:
 Functional Scenario (**FS**) → Logical Scenario (**LS**) → Concrete Scenario (**CS**).

Example of scenario structure in traffic disturbance scenarios

- Defines the highest-level qualitative scenario structure
- Decomposes scenarios into fundamental elements:

- **Road geometry**
- **Ego vehicle behavior**
- **Surrounding vehicle location**
- **Surrounding vehicle motion**

		Surrounding traffic participants behavior and approaching direction													
		Going straight				Lane change / Swerving				Turning					
		Same / Crossed		Oncoming		Same / Crossed		Oncoming		Same	Crossed	Oncoming			
Road geometry and subject vehicle behavior	Non-intersection	Going straight (Lane keep)	No.1	No.2	No.3	No.4	No.5	No.6	No.7			No.8			
		Lane change / Swerving	No.9	No.10	No.11	No.12	No.13	No.14	No.15			No.16			
	Merge	Going straight (Lane keep)	No.17	No.18	No.19	No.20	No.21	No.22							
		Lane change / Swerving	No.23	No.24	No.25	No.26	No.27	No.28							
	Branch	Going straight (Lane keep)	No.29	No.30	No.31	No.32	No.33	No.34							
		Lane change / Swerving	No.35	No.36	No.37	No.38	No.39	No.40							
Intersection	Going straight (Lane keep)	No.41	No.42	No.43	No.44	No.45	No.46	No.47	No.48	No.49					
	Turning	No.50	No.51	No.52	No.53	No.54	No.55	No.56	No.57	No.58					

58 FS for general vehicles

General road behaviors;
turning maneuver
oncoming vehicle
intersection

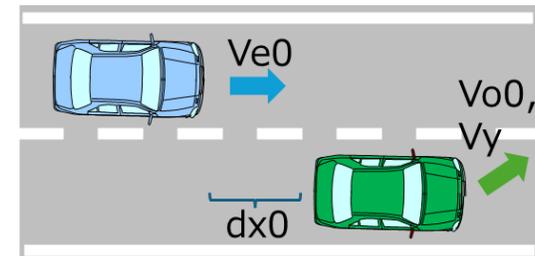

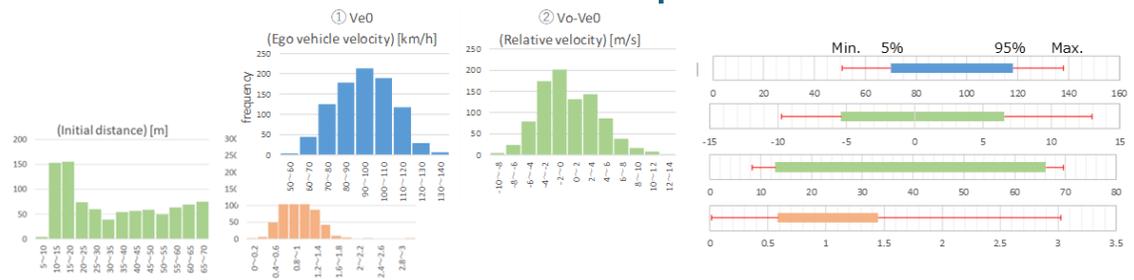

FS provides a comprehensive qualitative coverage of real-world driving situations.

Logical scenario (LS): Quantified parameter space

- Derived from structured FS
- **Assigns quantitative parameter ranges to each scenario**
- Defined using a data-driven approach

Parameter: velocity, distance,...

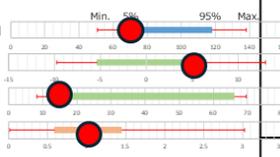

LS transforms qualitative structures into data-driven, quantitative parameter spaces.

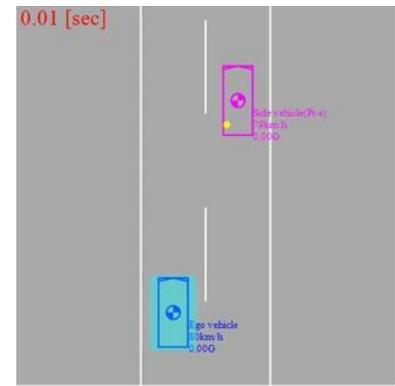

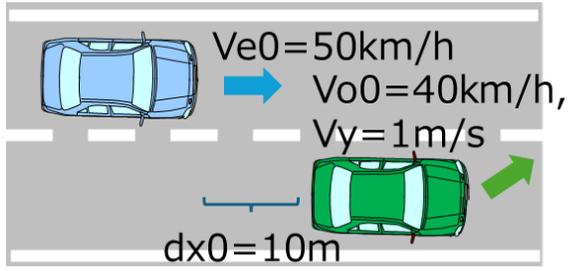

Concrete scenario (CS): Executable evaluation conditions

FS
LS
CS

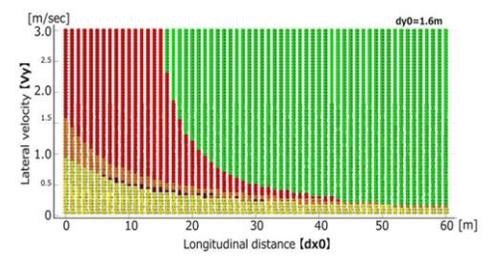

- Defined within the quantified parameter ranges of LS
- **Represents specific evaluation conditions used for testing and validation**
- Can be established using driver models or system performance models

Initial condition	Initial velocity	$Ve0 = X1 \text{ km/h}$ $Vo0 = X2 \text{ km/h}$
	Initial distance	$dx0 = Y1 \text{ m}$
Vehicle motion	Lateral motion	$Vy = Z \text{ m/s}$

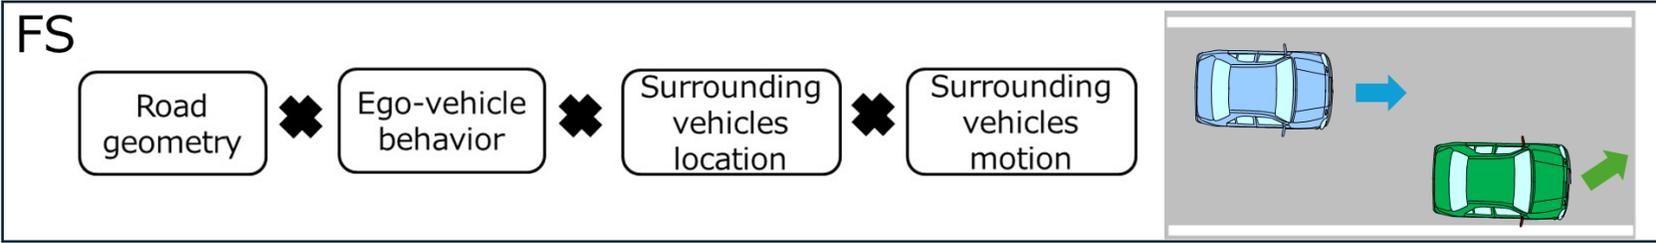

Collision occurrence

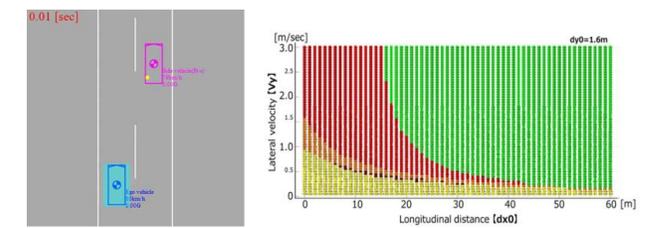

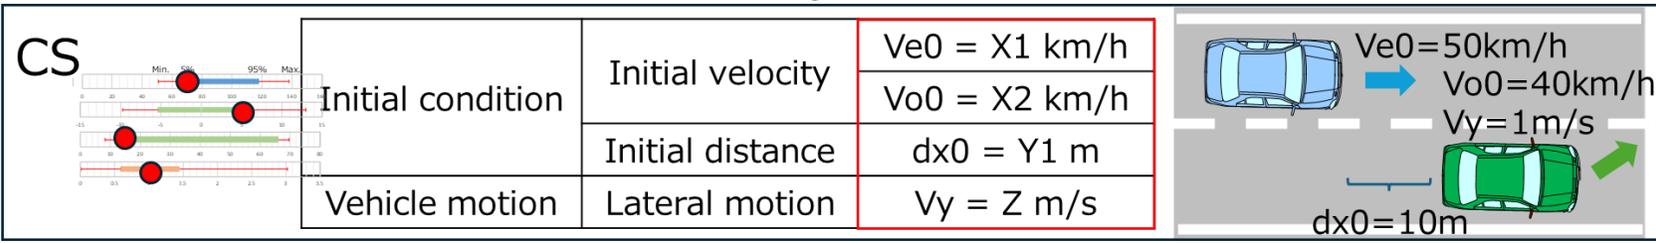

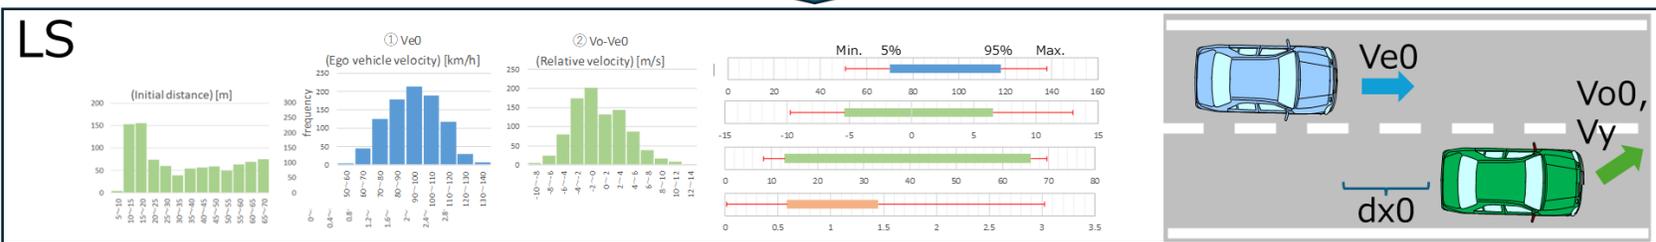

CS converts quantified scenario spaces into executable safety evaluation cases.

Integrated three-layer scenario framework

Scenario	Ego vehicle	Surrounding vehicle	Using dataset		Surrounding traffic participants behavior and surrounding direction		Testing	
			Early	Delayed	Early	Delayed	Early	Delayed
Scenario 1	Lead vehicle	Lead vehicle	100%	100%	100%	100%	100%	100%
	Lead vehicle	Lead vehicle	100%	100%	100%	100%	100%	100%
Scenario 2	Lead vehicle	Lead vehicle	100%	100%	100%	100%	100%	100%
	Lead vehicle	Lead vehicle	100%	100%	100%	100%	100%	100%
Scenario 3	Lead vehicle	Lead vehicle	100%	100%	100%	100%	100%	100%
	Lead vehicle	Lead vehicle	100%	100%	100%	100%	100%	100%

From qualitative structure to data-driven parameters to executable safety evaluation.

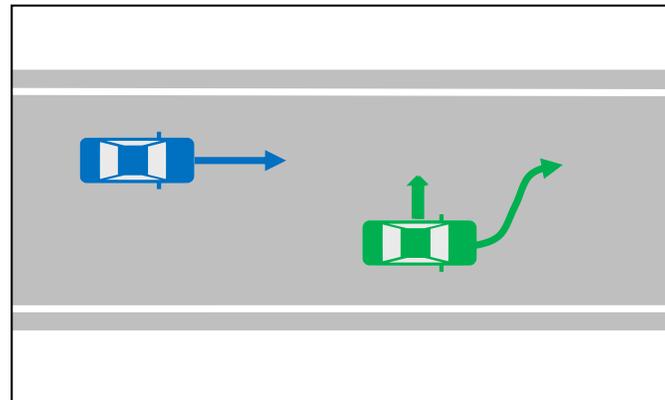

3. Data analysis

Case study: cut-in logical scenario

- Numerous Logical Scenarios can be derived from functional scenarios
- Each scenario involves a wide parameter space
- As a representative example, we focus on **cut-in scenarios** on highways

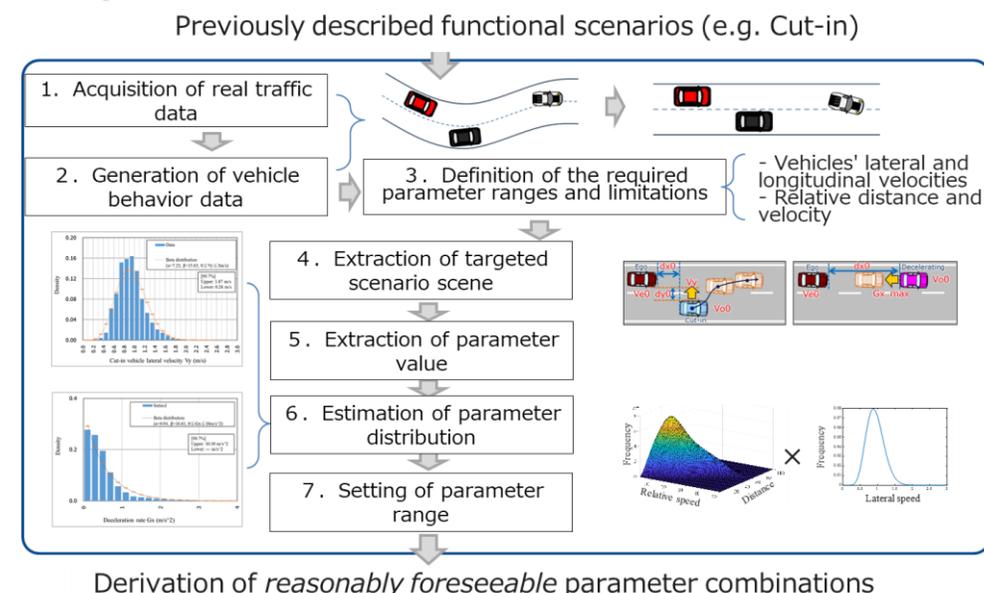

Objective:

Demonstrate how reasonably foreseeable parameter ranges can be defined for a specific logical scenario.

Cut-in is presented as a representative example of Logical Scenario analysis.

- Extract cut-in events from real-world traffic data
- Define Logical Scenarios using key parameters
- Basic range observation
- Additional analyses to identify reasonably foreseeable bounds:
 - Distribution modeling
 - Correlation analysis
 - Occurrence frequency estimation

H. Nakamura et al.,(2022).

Reasonably foreseeable ranges are derived through statistical modeling.

Real-world highway traffic data

- Data collected on **Japanese limited-access highways** (2017–2020)
- Sources:
 - Instrumented vehicles (professional/regular drivers)
 - Fixed roadway cameras
- Focus on speed range ≥ 60 km/h
- Extracted:
 - **903 cut-in scenarios**
- Straight road sections only
- Weather and road curvature effects excluded

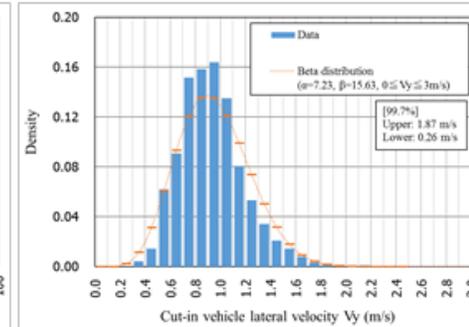

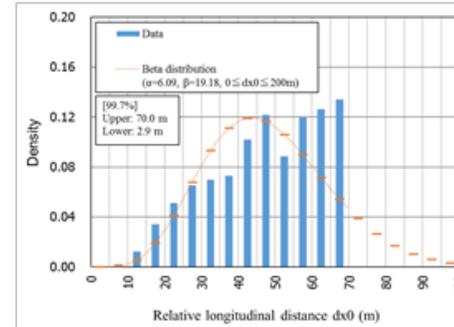

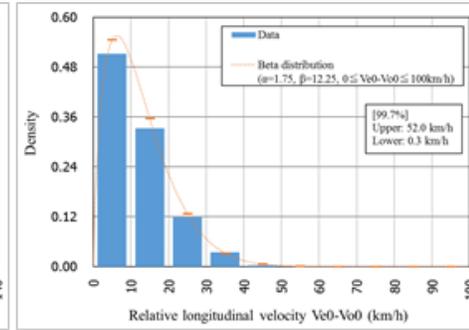

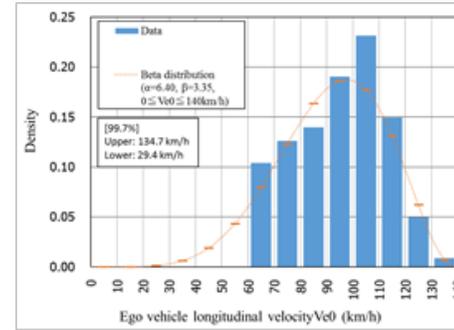

Logical Scenarios are grounded in large-scale real traffic observations.

Cut-in logical scenario: Observed parameter characteristics

- **Observed parameter ranges (≥ 60 km/h):**

- V_{e0} : 60–138 km/h
- Relative velocity: 0–50 km/h
- dx_0 : 8–70 m
- V_y : 0.2–2 m/s

- **Distribution insights:**

- Cut-ins most frequent around 100–110 km/h
- Drivers prefer small relative velocity (< 10 km/h)
- Larger longitudinal distance associated with higher relative speed
- Majority of maneuvers show low urgency (TTC typically > 7.5 s)

Observed cut-in maneuvers occupy a bounded and non-critical parameter region.

Parameter correlations

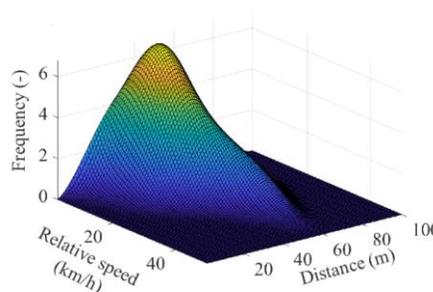

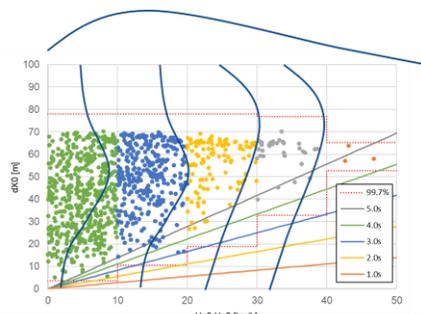

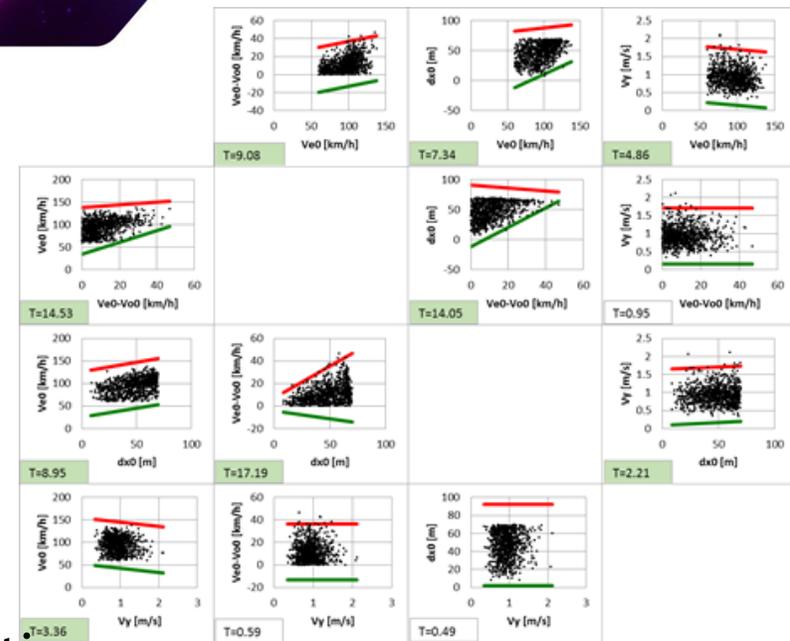

- Strong correlations among Ve_0 , $Vrel$, and dx_0
- Higher speed \rightarrow larger distance and relative velocity
- Vy largely behavior-dependent and weakly correlated
 \rightarrow Effective parameter space is structured, not arbitrary

Occurrence modeling

Joint occurrence frequency derived from correlated distributions

$$P_{cut-in} = p_1(Vrel, dx_0) \times p_2(Vy)$$

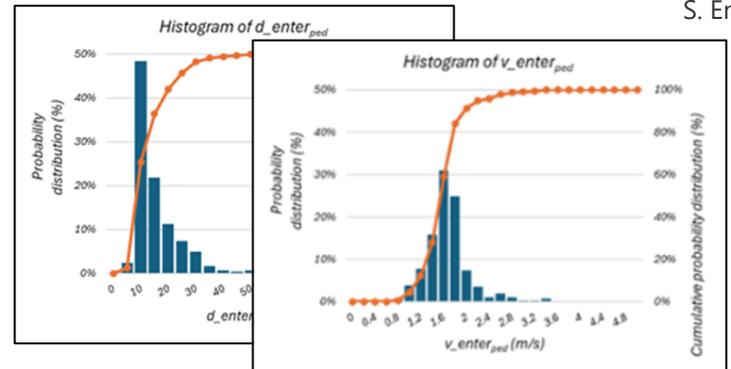

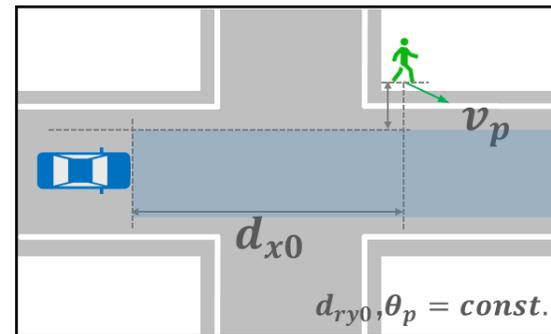

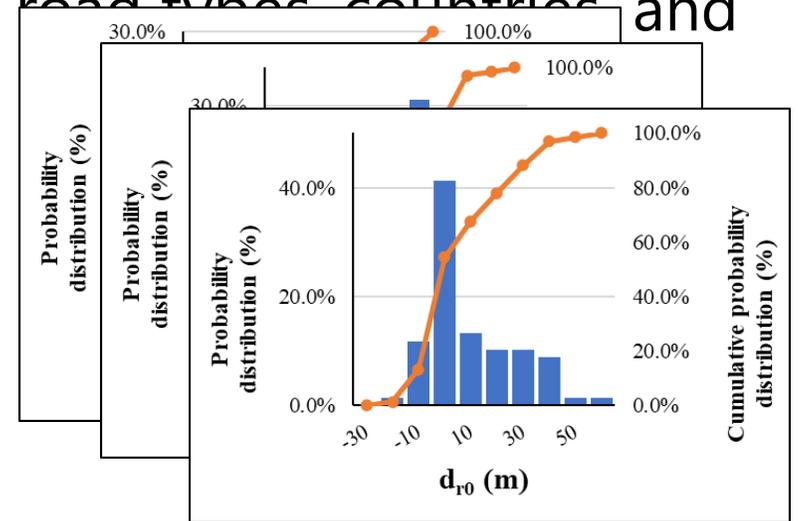

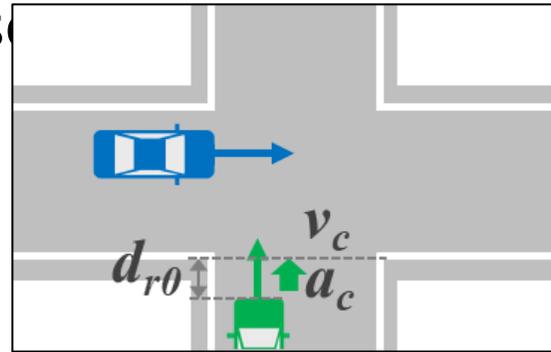

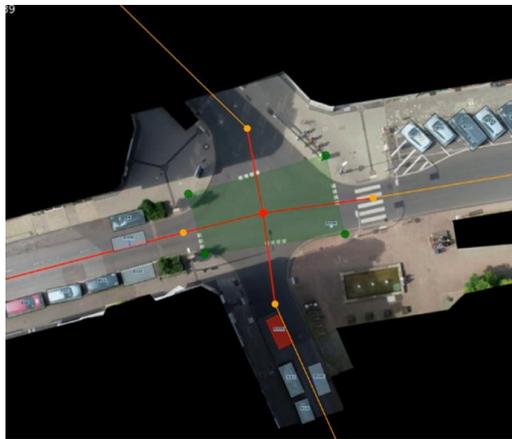

\rightarrow Enables probabilistic characterization of Logical Scenarios

Cut-in Logical Scenarios form a structured and statistically quantifiable parameter space.

Extension to urban scenarios using international data

The proposed methodology was also applied to international urban traffic datasets. The Logical Scenario framework is transferable across road types, countries, and different types of road users.

S. Endo et al. , (2025).

SAKURA project (2024).

Logical Scenarios define a quantifiable and transferable parameter space across different environments and road users.

4. Conclusion

Summary

- A structured three-layer scenario framework (FS–LS–CS) enables systematic and data-driven safety evaluation
- Logical Scenarios define a quantifiable and transferable parameter space across environments and road users

JARI's Contribution

- JARI has developed a comprehensive safety assessment process through the SAKURA Project

Future Direction

- Expanding the safety assessment framework to address emerging technologies, including AI-based systems

Thank you for your attention.
